Introduction to Linux Part 2b: basic scripting

Brett Milash and Wim Cardoen CHPC User Services

Overview

- Scripting in Linux
 - What is a script?
 - Why scripting?
 - Scripting languages + syntax
 - Bash/tcsh scripting exercises

What is a script?

- A script is a collection of linux commands that:
 - are stored in a file
 - the file **MUST** be executable (with one exception...)
 - commands are separated by:
 - either a carriage return (new line)
 - or by the semi colon (";")
 - executed sequentially until
 - the end of the file has been reached
 - or an error is met

Why scripting?

Scripting is a timesaver

The real question: When should you script?

Scenarios for scripting

 Using the batch system at CHPC (discussed in the talk on <u>Slurm Basics</u>)

 Automating pre- and post- processing of datasets

• Performing lots of menial, soul draining tasks efficiently and quickly (like building input files)

How long should you script?

HOW LONG CAN YOU WORK ON MAKING A ROUTINE TASK MORE EFFICIENT BEFORE YOU'RE SPENDING MORE TIME THAN YOU SAVE? (ACROSS FIVE YEARS)

http://xkcd.com/1205/

Task time saver calculator: <u>http://c.albert-thompson.com/xkcd/</u>

What to script in?

- Basic scripting needs can be done in the Bash shell or the Tcsh/Csh shell.
- If you have more complicated tasks to perform, then you should consider something more advanced (like <u>python</u>* or <u>matlab</u>).
- If your workload is computationally heavy, you should be consider to write your application in a compiled language (e.g. C/C++, Fortran, ...).

bash and tcsh

- A Shell is:
 - a. user interface to the OS's services
 - b. a layer (=> shell) around the kernel
 - c. a programming language
- CHPC currently supports 2 types of "shell-languages"/shells:
 - a. B(ourne) Again Shell (bash)
 - b. Csh/Tcsh shell
- Syntactic differences are significant (and quirky) => **NO MIXING ALLOWED**
- Some programs do not support different shells (rather rare)
- Very easy to switch between shells
- What shell do I currently use? *echo \$SHELL*

WHILE LEARNING TO SCRIPT, PICK ONE AND STICK WITH IT.

Can I change my shell? Yes, you can

- To change your default shell: go to chpc.utah.edu and login with your U of U credentials. You will be presented with your profile, which will have a link "Edit Profile". A new dialogue will show, and you will see an option to change shell. Change it to whatever you want, and save it. Changes will go through in about 15 minutes.
- (Also can be used to change your email on record, please do this if you change email addresses.)

Getting the exercise files

 For today's exercises, open a session to linuxclass.chpc.utah.edu and run the following commands:

Either:

cp ~u0424091/LinuxScripting1.tar.gz .

Or:

wget <u>https://www.chpc.utah.edu/presentations/LinuxScripting1.tar.gz</u>

Then:

tar xvfz LinuxScripting1.tar.gz

cd LinuxScripting1/

Pro tip: copy the URL above from our web page!

Write your first script (ex1)

- Open a file named ex1.sh (Bash) or ex1.csh (Tcsh) using Vi
- '#' character: start of a comment
- Top line always contains the 'she-bang' followed by the language interpreter:

'#!/bin/bash' (if you use Bash) or

'#!/bin/tcsh' (if you use Tcsh)

• Put the following content in a file:

echo " My first script:"

echo " My userid is:"

whoami

```
echo " I am in the directory:"
```

pwd

```
echo "Today's date:"
```

date

echo " End of my first script"

• Make the script executable and execute it:

chmod +x ex1.sh or chmod +x ex1.csh ./ex1.sh or ./ex1.csh

A comment about running programs

- When you execute a command, the shell must first find the program you want to run
- Either:
 - You tell the shell where to find the program (e.g. "./ex1.sh")
 - The shell must search for the program
- PATH environment variable
 - List of directories where the shell searches
 - Bash: echo \$PATH
 - Tcsh: echo \$path
- "which" command: shows where a command is found

Setting and Using Variables

#!/bin/bash
#set a variable (no spaces!)
VAR="hello bash!"
#print the variable
echo \$VAR

```
#make it permanent
export VAR2="string"
echo $VAR2
```

#remove VAR2
unset VAR2

```
#!/bin/tcsh
#set a variable
set VAR = "hello tcsh!"
#print the variable
echo $VAR
```

```
#make it permanent (no =)
setenv VAR2 "string"
echo $VAR2
```

#remove VAR2
unset VAR2

Be careful what you export! Don't overwrite something important!

Script Arguments

#!/bin/bash
ARG1=\$1
ARG2=\$2
#ARG3=\$3, and so on
echo \$ARG1
echo \$ARG1

```
#!/bin/tcsh
set ARG1 = $1
set ARG2 = $2
#set ARG3 = $3, so on
echo $ARG1
echo $ARG1
```

If the script is named "myscript.sh" (or "myscript.csh"), the script is executed with "./myscript.sh myarg1 myarg2 ... myargN" \$0 : returns the name of the script \$#: returns the # arguments

Using grep and wc

- grep searches files for test strings and outputs lines that contain the string
 - VERY fast, very easy way to parse output
 - can use regex (regular expression) and file patterns
 - use backslash (\) to search for special characters (e.g. to search for "!" use "\!")

grep "string" filename

 wc can count the number of lines in a file wc -l filename

Command line redirection (refresher)

- You can output to a file using the ">" operator.
 cat filename > outputfile
- You can append to the end of a file using ">>" cat filename >> outputfile
- You can redirect to another program with "|" cat filename | wc -1

Exercise 2

Write a script that takes a file as an argument, searches the file for exclamation points with grep, puts all the lines with exclamation points into a new file, and then counts the number of lines in the file. Use "histan-qe.out" as your test file.

Don't forget #!/bin/bash or #!/bin/tcsh

```
Variables - Bash style: VAR="string" (no spaces!)
Tcsh style: set VAR = "string"
```

Arguments - **\$1 \$2 \$3 ...**

Grep - grep 'string' filename

Counting Lines - wc -l filename

Solution to Exercise 2

#!/bin/bash
INPUT=\$1
grep '\!' \$INPUT > outfile
wc -l outfile

```
#!/bin/tcsh
set INPUT = $1
grep '\!' $INPUT > outfile
wc -l outfile
```

The output from your script should have been "34".
